Introduction

Khovanov homology

[\[Khovanov, 2000\]](#) A bigraded **chain complex** $C^{*,*}(D)$ (of abelian groups) for each link diagram D so that

$$Kh^{i,j}(D) := H^i(C^{*,j}(D))$$

is **invariant under Reidemeister moves**. This is nowadays called **Khovanov homology**.

↪ Relation to **TQFT** was pointed out.

Theorem 1.1 ([Kronheimer and Mrowka, 2011])

Khovanov homology **detects the unknot**.

[\[Lee, 2005\]](#) constructed a **variant**.

↪ a **concordance invariant** [Rasmussen, 2010].

[\[Bar-Natan, 2005\]](#) Khovanov complex in terms of **cobordisms**.

↪ Invariants for **tangles** instead of links.

↪ Changing **TQFT**, we get **variants** including **Lee homology** and **Bar-Natan homology**.

↪ **“universal” Khovanov homology**.

Vassiliev derivative

$\mathcal{X}^{(r)}$: the set of **singular links** with **exactly r double points**.

Definition ([Vassiliev, 1990] (implicit), [Birman, 1993], [Birman and Lin, 1993])

v : a knot invariant with values in A .

$\rightsquigarrow v^{(r)} : \mathcal{X}^{(r)} \rightarrow A$ by $v^{(0)} := v$ and **Vassiliev skein relation**:

$$v^{(r+1)} \left(\begin{array}{c} \nearrow \searrow \\ \bullet \\ \nwarrow \nearrow \end{array} \right) = v^{(r)} \left(\begin{array}{c} \nearrow \nearrow \\ \nwarrow \nwarrow \end{array} \right) - v^{(r)} \left(\begin{array}{c} \nwarrow \nwarrow \\ \nearrow \nearrow \end{array} \right) .$$

We call $v^{(r)}$ the **r -th (Vassiliev) derivative** of v .

Definition

v is called **of finite type** (or **Vassiliev type**) if $v^{(r)} \equiv 0$ for $r \gg 0$.

Slogan Finite-type invariants are **polynomials**.

cf. [Volić, 2006, Budney et al., 2017].

Theorem 1.2 ([Birman, 1993, Birman and Lin, 1993])

The **Taylor coefficients** of the Jones polynomial **at $t = 1$** are of finite type.

Question

Any relations between Khovanov homology and **finite type invariants**?

First goal

To understand Khovanov homology in view of **Vassiliev theory**.

Main result I

Main Theorem I (Ito, Y.)

Khovanov homology $Kh(-)$ extends to a **singular link invariant** so that

- 1 there is a morphism $\widehat{\Phi} : Kh^{i,j} \left(\begin{array}{c} \nearrow \\ \searrow \\ \nwarrow \\ \nearrow \end{array} \right) \rightarrow Kh^{i,j} \left(\begin{array}{c} \nearrow \\ \searrow \\ \nwarrow \\ \nearrow \end{array} \right)$ together with a **categorified Vassiliev skein relation**

$$\begin{array}{c} \dots \rightarrow Kh^{i,j} \left(\begin{array}{c} \nearrow \\ \searrow \\ \nwarrow \\ \nearrow \end{array} \right) \xrightarrow{\widehat{\Phi}} Kh^{i,j} \left(\begin{array}{c} \nearrow \\ \searrow \\ \nwarrow \\ \nearrow \end{array} \right) \rightarrow Kh^{i,j} \left(\begin{array}{c} \nearrow \\ \searrow \\ \bullet \\ \nearrow \end{array} \right) \\ \left. \begin{array}{c} \xrightarrow{\widehat{\Phi}} \\ \xrightarrow{\widehat{\Phi}} \end{array} \right\} Kh^{i+1,j} \left(\begin{array}{c} \nearrow \\ \searrow \\ \nwarrow \\ \nearrow \end{array} \right) \xrightarrow{\widehat{\Phi}} Kh^{i+1,j} \left(\begin{array}{c} \nearrow \\ \searrow \\ \nwarrow \\ \nearrow \end{array} \right) \rightarrow Kh^{i+1,j} \left(\begin{array}{c} \nearrow \\ \searrow \\ \bullet \\ \nearrow \end{array} \right) \rightarrow \dots \end{array}$$

- 2 the following categorified version of **FI relation**:

$$Kh^{*,*} \left(\begin{array}{c} \nearrow \\ \searrow \\ \bullet \\ \nearrow \end{array} \right) \cong 0 \quad .$$

Remark

The morphism $\widehat{\Phi}$, called the **genus-one morphism**, is different from the **concordance theoretic crossing-change** (e.g. see [Hedden and Watson, 2018]).

In fact, $\widehat{\Phi}$ is the **first concrete instance** of non-trivial maps of bidegree $(0, 0)$.

Meaning of FI relation

FI relation arises from comparison of the following two “paths:”

Main result II

Question

Can Vassiliev derivatives $Kh(\text{X})$ be computed independently of the resolutions?

Motivation

- $\text{Cone}(\widehat{\Phi})$ is large.
 \rightsquigarrow Difficult to compute examples.
- If two of the three homologies

$$Kh \left(\begin{array}{c} \nearrow \searrow \\ \nwarrow \nearrow \end{array} \right), \quad Kh \left(\begin{array}{c} \nwarrow \nearrow \\ \nearrow \searrow \end{array} \right), \quad \text{and} \quad Kh \left(\begin{array}{c} \nearrow \searrow \\ \nwarrow \nearrow \end{array} \right)$$

are computed, the other may also be determined thanks to the **categorified Vassiliev skein relation**.

Main Theorem II (Y. arXiv:2007.15867)

D : a **singular link diagram** with **exactly one double point**.

\rightsquigarrow There is a chain complex $C_{\text{crx}}^{*,*}(D)$, called the **crux complex**, together with a (graded) endomorphism

$$\Xi : C_{\text{crx}}^{*-2, *-2}(D) \rightarrow C_{\text{crx}}^{*+2, *+4}(D)$$

such that

$$C_{Kh} \left(\begin{array}{c} \nearrow \searrow \\ \nwarrow \nearrow \end{array} \right) \simeq \text{Cone}(\Xi) \quad .$$

Slogan Main Theorem II computes the **1st Vassiliev derivative** of $Kh(-)$.

Today's plan

1 Introduction

- Khovanov homology
- Vassiliev derivative
- Vassiliev derivatives of knot homologies
- Main result I
- Main result II

2 Khovanov homology

- The category $Cob_2^{\ell}(Y_0, Y_1)$
- Singular link-like graph
- Smoothings of link-like graphs
- Multi-fold complexes
- The multi-fold complex of smoothings

- Universal Khovanov complexes
- Fundamental cofiber sequences
- Applying TQFTs
- Invariance

3 The first Vassiliev derivative

- Overview
- Twisted action
- Crux complexes
- Absolute exact sequences
- Key exact sequence
- Generalized 9-lemma
- Proof of Main Theorem II

4 Application

- Reducible crossing
- Homology of twist knots

Khovanov homology

The category $Cob_2^{\ell}(Y_0, Y_1)$

Y_0, Y_1 : compact oriented 0-manifolds.

Definition

Define $Cob_2(Y_0, Y_1)$ to be a category such that

- objects are (oriented) **1-cobordisms** $W : Y_0 \rightarrow Y_1$;
- morphisms are (diffeo. classes of) **2-cobordisms with corners** (aka. **2-bordisms**).
- composition is given in terms of **gluing**.

2-bordisms $S : W_0 \rightarrow W_1 \in Cob_2(Y_0, Y_1)$:

Definition

Define $Cob_2^{\ell}(Y_0, Y_1)$ to be the **k -linear additive category** generated by $Cob_2(Y_0, Y_1)$ subject to the following relations:

S-relation $S \amalg S^2 \sim 0$ for $S : W_0 \rightarrow W_1$;

T-relation $S \amalg T^2 \sim 2 \cdot S$ for $S : W_0 \rightarrow W_1$;

4Tu-relation

Remark

The morphisms of $Cob_2^{\ell}(Y_0, Y_1)$ are graded by **Euler characteristics**.

$Cob_2^{\ell}(Y_0, Y_1)$: a **graded k -linear category**.

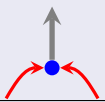

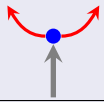

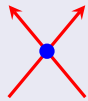

Singular link-like graph

Definition

A **singular link-like graph** is a planar graph $G = \{E(G) \rightrightarrows V(G)\}$, say $V^r(G)$ the set of r -valent vertices, together with data

- a subset $c(G) \subset V^4(G)$ of **crossings** with **signs**;
 \rightsquigarrow elements of $c^\sharp(G) := V(G) \setminus c(G)$: **double points**;
- a subset $E^w(G) \subset E(G)$ of **wide edges**;

such that each vertex is locally depicted as follows:

					
source of a wide edge	target of a wide edge	bivalent vertex	positive crossing	negative crossing	double point

In particular, a **singular link diagram** is nothing but a singular link-like graph without wide edges.

Convention

- Vertices of the left three types are omitted from pictures.
- Bivalent vertices are removed whenever possible.

Remark

If $V^4(G) = \emptyset$, then the **union of non-wide edges** is a **smooth 1-manifold**.

Smoothings of link-like graphs

Definition

A map $\alpha : V^4(G) \rightarrow \mathbb{Z}$ is said to **lie in the effective range** if

- $0 \leq \alpha(v) \leq 1$ for positive crossings v ;
- $-1 \leq \alpha(v) \leq 0$ for negative crossings v ;
- $-2 \leq \alpha(v) \leq 1$ for double points v .

In this case, define the **α -smoothing** G_α by replacing quadri-valent vertices as follows:

$v \in V^4(G)$	$\alpha(v) = -2$	$\alpha(v) = -1$	$\alpha(v) = 0$	$\alpha(v) = 1$

Definition

For each $\alpha : V^4(G) \rightarrow \mathbb{Z}$, define $|G_\alpha| \in \mathbf{Cob}_2^l(\emptyset, \emptyset)$ as follows:

α :eff. $|G_\alpha|$: the union of non-wide edges of G_α

$\rightsquigarrow |G_\alpha|$ (+ orientation) is an object of $\mathbf{Cob}_2(\emptyset, \emptyset)$.

α :non-eff. $|G_\alpha| = 0$.

Example

$$\left| \begin{array}{c} \nearrow \\ \searrow \\ \nwarrow \\ \nearrow \end{array} \right| = \begin{array}{c} \nearrow \\ \searrow \\ \nwarrow \\ \nearrow \end{array}, \quad \left| \begin{array}{c} \frown \\ \uparrow \\ \smile \end{array} \right| = \begin{array}{c} \frown \\ \uparrow \\ \smile \end{array} .$$

Remark

Precisely, we need a **checkerboard coloring** for G to determine the orientation on $|G_\alpha|$. Details are omitted in this talk.

Multi-fold complexes

Idea: construct **Khovanov complex** of G by **categorically** summing up all **states** (i.e. α in the effective range).

Khovanov discussed **cubes** of states.

\rightsquigarrow We generalize them to consider **double points**.

\mathcal{A} : an additive category, S : a finite set.

Definition

An **S -fold complex** in \mathcal{A} consists of

- a family of objects $\{X^\alpha\}_\alpha$ of \mathcal{A} indexed by elements α of the free abelian group generated by S ;
 - for each element $a \in S$, a morphism $d_a = d_a^\alpha : X^\alpha \rightarrow X^{\alpha+1}$;
- which satisfy the following relations:

$$d_a^2 = 0, \quad d_a d_b = d_b d_a \quad (a \neq b) \quad .$$

Definition

X^\bullet, Y^\bullet : S -fold complexes in \mathcal{A} .

\rightsquigarrow a **morphism** $f : X^\bullet \rightarrow Y^\bullet$ of **S -fold complexes** consists of a morphism $f^\alpha : X^\alpha \rightarrow Y^\alpha$ for each $\alpha \in \mathbb{Z}S$ with $f d_a = d_a f$.

\rightsquigarrow **$\text{MCh}_S(\mathcal{A})$** : the category of S -fold complexes.

Remark

If \mathcal{A} is additive (resp. abelian), then so is $\text{MCh}_S(\mathcal{A})$.

Example

- 1 For $S = \{*\}$, $\text{MCh}_{\{*\}}(\mathcal{A}) \cong \text{Ch}(\mathcal{A})$.
- 2 If $S = \{H, V\}$, $\text{MCh}_{\{H, V\}}(\mathcal{A})$ is identified with the category of **bicomplexes** in \mathcal{A} .
- 3 If $S = S_1 \amalg S_2$, then there is a canonical equivalence

$$\text{MCh}_{S_1 \amalg S_2}(\mathcal{A}) \simeq \text{MCh}_{S_1}(\text{MCh}_{S_2}(\mathcal{A})) \quad .$$

The multi-fold complex of smoothings

Definition

Define three morphisms in $Cob_2^l(-, -)$ as follows:

$$\delta_- := \left[\text{box with } \left. \begin{array}{c} \text{---} \\ \text{---} \end{array} \right\} \right] : \left[\begin{array}{c} \text{---} \\ \text{---} \end{array} \right] \rightarrow \left[\begin{array}{c} \text{---} \\ \text{---} \end{array} \right] , \quad \delta_+ := \left[\text{box with } \left. \begin{array}{c} \text{---} \\ \text{---} \end{array} \right\} \right] : \left[\begin{array}{c} \text{---} \\ \text{---} \end{array} \right] \rightarrow \left[\begin{array}{c} \text{---} \\ \text{---} \end{array} \right] ,$$

$$\Phi := \left[\text{box with circle} \right] - \left[\text{box with bump} \right] : \left[\begin{array}{c} \text{---} \\ \text{---} \end{array} \right] \rightarrow \left[\begin{array}{c} \text{---} \\ \text{---} \end{array} \right] .$$

Lemma 2.1

$\Phi\delta_- = 0$ and $\delta_+\Phi = 0$

Proof

$$\left[\text{box with circle} \right] \left[\text{box with } \left. \begin{array}{c} \text{---} \\ \text{---} \end{array} \right\} \right] \cong \left[\text{box with bump} \right] \left[\text{box with } \left. \begin{array}{c} \text{---} \\ \text{---} \end{array} \right\} \right] , \quad \left[\text{box with } \left. \begin{array}{c} \text{---} \\ \text{---} \end{array} \right\} \right] \left[\text{box with circle} \right] \cong \left[\text{box with bump} \right] \left[\text{box with } \left. \begin{array}{c} \text{---} \\ \text{---} \end{array} \right\} \right] . \quad \square$$

Definition

Define a $V^4(G)$ -fold complex $Sm(G)^\bullet$ in $Cob_2^l(\emptyset, \emptyset)$ by $Sm(G)^\alpha := |G_\alpha|$ with differentials given as follows:

- if v is a double point, d_v is given by

$$\dots \rightarrow 0 \rightarrow \left[\begin{array}{c} \text{---} \\ \text{---} \end{array} \right] \xrightarrow{-\delta_-} \left[\begin{array}{c} \text{---} \\ \text{---} \end{array} \right] \xrightarrow{\Phi} \left[\begin{array}{c} \text{---} \\ \text{---} \end{array} \right] \xrightarrow{-\delta_+} \left[\begin{array}{c} \text{---} \\ \text{---} \end{array} \right] \rightarrow 0 \rightarrow \dots$$

- if v is a negative crossing, d_v is given by

$$\dots \rightarrow 0 \rightarrow \left[\begin{array}{c} \text{---} \\ \text{---} \end{array} \right] \xrightarrow{\delta_-} \left[\begin{array}{c} \text{---} \\ \text{---} \end{array} \right] \rightarrow 0 \rightarrow \dots ;$$

- if v is a positive crossing, d_v is given by

$$\dots \rightarrow 0 \rightarrow \left[\begin{array}{c} \text{---} \\ \text{---} \end{array} \right] \xrightarrow{-\delta_+} \left[\begin{array}{c} \text{---} \\ \text{---} \end{array} \right] \rightarrow 0 \rightarrow \dots .$$

Universal Khovanov complexes

Total complexes of bicomplexes:

$$\begin{array}{ccc} \{\text{bicomplexes}\} & \xrightarrow{\text{anti-comm.}} & \{\text{double complexes}\} & \xrightarrow{\text{Tot}} & \{\text{complexes}\} \\ X^{i,j} & \longmapsto & X^{i,j} & \longmapsto & \bigoplus_{i+j=n} X^{i,j} \\ d_H, d_V & \longmapsto & d_H, (-1)^i d_V & \longmapsto & \sum d_H + (-1)^i d_V \end{array}$$

Definition

S : a **totally ordered set**.

\rightsquigarrow For a **bounded** S -fold complex X , define $\text{Tot}(X)$ as a complex given by

$$\text{Tot}(X)^n := \bigoplus_{|\alpha|=n} X^\alpha, \quad d_{\text{tot}} := \sum_{a \in S} (-1)^{\sum_{b < a} \alpha(b)} d_a, \quad ,$$

here $|\alpha| := \sum_a \alpha(a)$.

Remark

The isomorphism type of $\text{Tot}(X)$ does not depend on total orders on S . In fact, there is a “universal” sign convention.

Definition

For a singular link-like graph G , we define the **universal Khovanov complex** as

$$\llbracket G \rrbracket := \text{Tot}(\text{Sm}(G)^\bullet) \quad .$$

Fundamental cofiber sequences

Definition

X^\bullet : an S -fold complex.

- For $\alpha_0 \in \mathbb{Z}S$, we write $X[\alpha_0]^\bullet$ the S -fold complex with

$$X[\alpha_0]^\alpha := X^{\alpha - \alpha_0}, \quad d_{X[\alpha_0],a} := (-1)^{\alpha_0(a)} d_{X,a}.$$

$X[\alpha_0]$ is called the **shift** of X^\bullet by α_0 .

- For $a \in S$ and $r \in \mathbb{Z}$, we write $\sigma_a^{\leq r} X^\bullet$ (resp. $\sigma_a^{\geq r} X^\bullet$, etc...) the S -fold complex given by

$$\sigma_a^{\leq r} X^\alpha := \begin{cases} X^\alpha & \alpha(a) \leq r \text{ (resp. } \alpha(a) \geq r, \text{ etc...),} \\ 0 & \text{otherwise,} \end{cases}$$

$$d_{\sigma_a^{\leq r} X, a}^\alpha := \begin{cases} d_{X, a}^\alpha & \alpha(a) \leq r - 1 \text{ (resp. } \alpha(a) \geq r, \text{ etc...),} \\ 0 & \text{otherwise.} \end{cases}$$

$\sigma_a^{\leq r} X^\bullet$ is called the **stupid truncation** of X^\bullet along a at r .

Proposition 2.2

X^\bullet : a bounded S -fold complex, $a_0 \in S$, $r \in \mathbb{Z}$.

\rightsquigarrow Define $\varphi : (\sigma_{a_0}^{\leq r-1} X)[a_0] \rightarrow \sigma_{a_0}^{\geq r} X \in \mathbf{MCh}_S^b(\mathcal{A})$ by

$$\begin{array}{ccccccc} \dots & \longrightarrow & X^{\alpha+(r-2)a_0} & \xrightarrow{d_{a_0}} & X^{\alpha+(r-1)a_0} & \longrightarrow & 0 \longrightarrow \dots \\ & & \downarrow \varphi^{\alpha+(r-1)a_0} & & \downarrow \varphi^{\alpha+ra_0}=d_{a_0} & & \downarrow \varphi^{\alpha+(r+1)a_0} \\ \dots & \longrightarrow & 0 & \longrightarrow & X^{\alpha+ra_0} & \xrightarrow{d_{a_0}} & X^{\alpha+(r+1)a_0} \xrightarrow{d_{a_0}} \dots \end{array}$$

Then, for the induced morphism

$$\widehat{\varphi} : \text{Tot}((\sigma_{a_0}^{\leq r-1} X)[a_0]^\bullet) \rightarrow \text{Tot}(\sigma_{a_0}^{\geq r} X^\bullet),$$

we have an isomorphism $\text{Tot}(X^\bullet) \cong \text{Cone}(\widehat{\varphi})$.

Fundamental cofiber sequences

Proposition 2.3

For every **singular link-like graph** D , there are isomorphisms

$$\begin{aligned} \llbracket \text{X} \rrbracket &\cong \text{Cone} \left(\llbracket \text{X} \rrbracket \xrightarrow{\hat{\delta}_-} \llbracket \text{X} \rrbracket \right) , \\ \llbracket \text{X} \rrbracket &\cong \text{Cone} \left(\llbracket \text{X} \rrbracket \xrightarrow{\hat{\delta}_+} \llbracket \text{X} \rrbracket \right) [1] , \\ \llbracket \text{X} \rrbracket &\cong \text{Cone} \left(\llbracket \text{X} \rrbracket \xrightarrow{\hat{\Phi}} \llbracket \text{X} \rrbracket \right) . \end{aligned}$$

Proof

By direct computations, we obtain

$$\begin{aligned} \text{Tot} \left(\sigma_{v_-}^{\leq -1} \text{Sm} \left(\llbracket \text{X} \rrbracket \right) [v_-]^\bullet \right) &\cong \llbracket \text{X} \rrbracket , \\ \text{Tot} \left(\sigma_{v_-}^{\geq 0} \text{Sm} \left(\llbracket \text{X} \rrbracket \right)^\bullet \right) &\cong \llbracket \text{X} \rrbracket [1] , \\ \text{Tot} \left(\left(\sigma_{v_+}^{\leq 0} \text{Sm} \left(\llbracket \text{X} \rrbracket \right) \right) [v_+]^\bullet \right) &\cong \llbracket \text{X} \rrbracket [1] , \\ \text{Tot} \left(\sigma_{v_+}^{\geq 1} \text{Sm} \left(\llbracket \text{X} \rrbracket \right)^\bullet \right) &\cong \llbracket \text{X} \rrbracket [1] , \\ \text{Tot} \left(\left(\sigma_{v_\times}^{\leq -1} \text{Sm} \left(\llbracket \text{X} \rrbracket \right) \right) [v_\times]^\bullet \right) &\cong \llbracket \text{X} \rrbracket , \\ \text{Tot} \left(\sigma_{v_\times}^{\geq 0} \text{Sm} \left(\llbracket \text{X} \rrbracket \right)^\bullet \right) &\cong \llbracket \text{X} \rrbracket . \end{aligned}$$

\rightsquigarrow we get the result by Proposition 2.2. □

Corollary 2.4

For every **ordinary link diagram** D , $\llbracket D \rrbracket$ agrees with the one defined in [Bar-Natan, 2005].

Applying TQFTs

Recall a **2-dim. TQFT** is nothing but a **Frobenius algebra**.

Fact

For $h, t \in k$, endow a Frobenius algebra structure on

$C_{h,t} = k[x]/(x^2 - hx - t)$ by

$$\begin{aligned} \Delta(1) &= 1 \otimes x + x \otimes 1 - h1 \otimes 1, & \Delta(x) &= x \otimes x + t1 \otimes 1 \\ \varepsilon(1) &= 0, & \varepsilon(x) &= 1 \end{aligned}$$

Then, it gives rise to a k -linear functor

$$Z_{h,t} : \mathit{Cob}_2^{\ell}(\emptyset, \emptyset) \rightarrow \mathbf{Mod}_k \quad .$$

Example

For every **link diagram** D ,

$$HZ_{0,0}[[D]] \cong Kh(D), \quad HZ_{1,0}[[D]] \cong BN(D), \quad HZ_{0,1}[[D]] \cong Lee(D)$$

Remark

In the case $h = t = 0$, $C_{0,0}$ is **graded** so that

$$\deg 1 = 1, \quad \deg x = -1 \quad .$$

↪ The TQFT $Z_{0,0}$ **respects gradings**.

cf. the Euler grading on $\mathit{Cob}_2^{\ell}(\emptyset, \emptyset)$.

↪ **Second grading on Kh** , called the **q -grading**.

Invariance

Theorem 2.5 (Ito, Y. 2020)

The universal Khovanov complex $[[D]]$ is **invariant** under the **moves of singular link diagrams** up to chain homotopy equivalences.

↔ Applying $Z_{h,t}$, we get extensions of

- Khovanov homology,
- Lee homology, and
- Bar-Natan homology

to singular links.

Approach: elementary moves of double points:

Since invariance under **Reidemeister moves** is known, the result essentially follows from Proposition 2.3 and the following.

Proposition 2.6

The **genus-one morphism** $\hat{\Phi}$ is **invariant** under the moves above; i.e. there are homotopy commutative squares

The first Vassiliev derivative

Overview

Throughout the section, we fix

G : a **singular link-like graph** with a **unique double point**.

Problem

Compute $Kh(G)$.

Approach

- Construct a complex $[[G]]_{\text{crx}}$ in $\text{Cob}_2^{\ell}(\emptyset, \emptyset)$, called the **crux complex**;
 $\rightsquigarrow C_{\text{crx}}(G) := Z_{0,0}[[G]]_{\text{crx}}$.
- Define $\Xi : [[G]]_{\text{crx}}[2] \rightarrow [[G]]_{\text{crx}}[-2]$.
- Show $[[G]] \simeq \text{Cone}(\Xi)$.
 $\rightsquigarrow Kh(G) \cong H^* \text{Cone}(Z_{0,0}(\Xi))$.

Remark

- Ξ has an **explicit description**.
- $[[G]]_{\text{crx}}$ is at least **four times smaller** than $[[G]]$.
 \rightsquigarrow Reduce the size of complexes computing $[[G]]$.

Remark

Regarding **higher derivatives** of Kh , for a general G with exactly r **double points**, we have a **spectral sequence**

$$E_1 \cong (1^{\text{st}}\text{-derivatives of } Kh) \Rightarrow Kh(G) \quad .$$

Twisted action

Recall in the category of **cobordisms**, the interval I is a **module** and a **comodule** over the circle S^1 :

$$\mu := \text{[diagram]} : I \otimes S^1 \rightarrow I, \quad \Delta := \text{[diagram]} : I \rightarrow I \otimes S^1$$

Proposition 3.1

The following also give other S^1 -**module/comodule structures** on I up to Bar-Natan's **4Tu-relation**:

$$\tilde{\mu} := \text{[diagram]} - \text{[diagram]}, \quad \tilde{\Delta} := \text{[diagram]} - \text{[diagram]} .$$

We call them **twisted action/coaction** of S^1 on I .

Example

$C_{0,0} = k[x]/(x^2)$: The Frobenius algebra **for Khovanov homology**.

\rightsquigarrow The **twisted action/coaction** are

$$\begin{array}{lcl} \tilde{\mu} : C_{0,0} \otimes C_{0,0} \rightarrow C_{0,0} & , & \tilde{\Delta} : C_{0,0} \mapsto C_{0,0} \otimes C_{0,0} \\ a \otimes 1 \mapsto a & & 1 \mapsto 1 \otimes x - x \otimes 1 \\ a \otimes x \mapsto -ax & & x \mapsto x \otimes x \end{array} .$$

Remark

In the situation above, $\tilde{\mu}$ and $\tilde{\Delta}$ are homogeneous with respect to the **Euler degrees** and

$$\deg \tilde{\mu} = \deg \tilde{\Delta} = \deg \mu = \deg \Delta = -1 .$$

Crux complexes

Definition

A map $\alpha : c(G) \rightarrow \mathbb{Z}$ is called a **G -crux map** if

- 1 α lies in the effective range (with $\alpha(\text{double pt.}) := 0$);
- 2 the edges adjacent to the (unique!) double point lie in the same connected component in $|G_\alpha|$.

Notation

$$|G_\alpha|_{\text{crx}} := \begin{cases} |G_\alpha| & \alpha: G\text{-crux map,} \\ 0 & \text{otherwise.} \end{cases}$$

Twisted arcs

The “**upper half**” of the component encircling the double point:

Definition

Define a $c(G)$ -fold complex $\text{CrX}(G)^\bullet$ by

$$\text{CrX}(G)^\alpha := |G_\alpha|_{\text{crx}}$$

with the differentials given in the same way as $\text{Sm}(G)^\bullet$ with **twisted actions/coactions** on **twisted arcs**:

$$\tilde{\mu} : \begin{array}{c} \text{blue arc} \\ \text{red arc} \end{array} \rightarrow \begin{array}{c} \text{blue arc} \\ \text{blue arc} \end{array}, \quad \tilde{\Delta} : \begin{array}{c} \text{blue arc} \\ \text{blue arc} \end{array} \rightarrow \begin{array}{c} \text{blue arc} \\ \text{red arc} \end{array} .$$

Crux complexes

In order to verify $\text{CrX}(G)^\bullet$ is actually an $c(G)$ -fold complex, we have to check the following.

Lemma 3.2

For $v \neq w \in c(G)$, the following commutes:

$$\begin{array}{ccc}
 |G_\alpha|_{\text{crx}} & \xrightarrow{d_v} & |G_{\alpha+v}|_{\text{crx}} \\
 d_w \downarrow & & \downarrow d_w \\
 |G_{\alpha+w}|_{\text{crx}} & \xrightarrow{d_w} & |G_{\alpha+v+w}|_{\text{crx}}
 \end{array} \cdot$$

Proof

CASE $d_v, d_w \in \{\mu, \Delta\}$: same as $\text{Sm}(-)^\bullet$.

CASE $d_v, d_w \in \{\mu, \tilde{\mu}\}$ **or** $d_v, d_w \in \{\Delta, \tilde{\Delta}\}$: The result follows from the **(co)associativity** of $\tilde{\mu}$ and $\tilde{\Delta}$.

The other non-trivial cases: It remains to discuss

They are verified e.g. as = 0

□

Crux complexes

Definition

The complex $[[G]]_{\text{crx}} := \text{Tot}(\text{Crx}(G)^\bullet)$ is called the **crux complex** of G .

In particular, write

$$C_{\text{crx}}(G) := Z_{0,0}[[G]]_{\text{crx}} \quad .$$

Example

$$[[G]]_{\text{crx}} := \left[\begin{array}{c} \text{Diagram of a red trefoil knot with a blue dot} \end{array} \right]_{\text{crx}} \cong \text{Tot} \left(\begin{array}{ccc} \begin{array}{c} \text{Diagram of a red and blue trefoil knot} \\ \xrightarrow{\tilde{\mu}} \\ \text{Diagram of a red and blue trefoil knot} \end{array} & & \\ \begin{array}{c} \downarrow \mu \\ \text{Diagram of a red and blue trefoil knot} \end{array} & & \downarrow \\ \text{Diagram of a red and blue trefoil knot} & \longrightarrow & 0 \end{array} \right)$$

\rightsquigarrow We obtain $H^*C_{\text{crx}}(G) = 0$ except

$$H^{-2}C_{\text{crx}}(G) \cong \langle x \otimes x \rangle \cong \mathbb{Z} ,$$

$$\begin{aligned} H^{-1}C_{\text{crx}}(G) &\cong C_{0,0}^{\oplus 2} / \langle (1, -1), (x, x), (x, -x) \rangle \\ &\cong \mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z} . \end{aligned}$$

Remark

In the example above, the summands in $H^*C_{\text{crx}}(G)$ are homogeneous with respect to the q -degree.

Absolute exact sequences

Strategy

To relate $[[G]]_{\text{crx}}$ with $[[G]]$, we want to place them in a single **exact sequence**.

YET, $\text{Cob}_2^{\ell}(\emptyset, \emptyset)$ is **not abelian**.

↪ What is **exactness**?

Definition

A sequence

$$\dots \xrightarrow{f^{i-1}} X^i \xrightarrow{f^i} X^{i+1} \xrightarrow{f^{i+1}} \dots$$

in a (pre-)additive category \mathcal{A} is said to be **absolutely exact** if the following conditions are satisfied:

- 1 $f^{i+1}f^i = 0$ for every $i \in \mathbb{Z}$;
- 2 it is contractible as a chain complex.

Remark

TFAE:

- $\{X^i, f^i\}$ is absolutely exact;
- For every functor $F : \mathcal{A} \rightarrow \mathcal{V}$ with \mathcal{V} abelian, $\{FX^i, Ff^i\}$ is exact.

Example

- 1 Absolute exact sequence of length 1 = zero object
- 2 Absolute exact sequence of length 2 = isomorphism
- 3 Absolute exact sequence of length 3 = split short exact sequence

Key exact sequence

Proposition 3.3 (cf. RI-moves by [Bar-Natan, 2005])

The following are **split short exact sequences**:

$$\begin{aligned}
 0 \rightarrow I \xrightarrow{\Delta} I \otimes S^1 \xrightarrow{\tilde{\mu}} I \rightarrow 0 \quad , \\
 0 \rightarrow I \xrightarrow{\tilde{\Delta}} I \otimes S^1 \xrightarrow{\mu} I \rightarrow \quad .
 \end{aligned}$$

Proof

First, observe that the S -relation implies

$$\mu \circ (I \otimes \eta) = \tilde{\mu} \circ (I \otimes \eta) = (I \otimes \varepsilon) \circ \Delta = (I \otimes \varepsilon) \circ \tilde{\Delta} = \text{id}_I \quad .$$

In addition, the $4Tu$ -relation yields

$$\Delta \circ (I \otimes \varepsilon) + (I \otimes \eta) \circ \tilde{\mu} = \tilde{\Delta} \circ (I \otimes \varepsilon) + (I \otimes \eta) \circ \mu = \text{id}_{I \otimes S^1} \quad .$$

□

Corollary 3.4

The following are absolutely exact sequences:

Proof

The first one is obvious since $\Phi = 0$ in this case.

The second follows from the observation $\Phi = \tilde{\Delta}\tilde{\mu}$. □

Key exact sequence

Definition

For $\alpha : c(G) \rightarrow \mathbb{Z}$, define morphisms

$$\iota^\alpha : \left[\begin{array}{c} \text{X} \\ \alpha \\ \text{crx} \end{array} \right] \rightarrow \left[\begin{array}{c} \text{Sm} \\ \alpha \end{array} \right], \quad \pi^\alpha : \left[\begin{array}{c} \text{Sm} \\ \alpha \end{array} \right] \rightarrow \left[\begin{array}{c} \text{X} \\ \alpha \\ \text{crx} \end{array} \right]$$

by

$$\iota^\alpha := \begin{cases} \tilde{\Delta} : \text{Diagram} \rightarrow \text{Diagram} \\ 0 \end{cases} \quad \pi^\alpha := \begin{cases} \tilde{\mu} : \text{Diagram} \rightarrow \text{Diagram} \\ 0 \end{cases} \quad \begin{array}{l} \alpha: G\text{-crux map,} \\ \text{otherwise,} \end{array}$$

Lemma 3.5

The families $\iota = \{\iota^\alpha\}_\alpha$ and $\pi = \{\pi^\alpha\}_\alpha$ form the following morphisms of $c(G)$ -fold complexes respectively:

$$\iota : \text{CrX} \left(\begin{array}{c} \text{X} \\ \bullet \end{array} \right) \rightarrow \text{Sm} \left(\begin{array}{c} \text{Sm} \\ \bullet \end{array} \right), \quad \pi : \text{Sm} \left(\begin{array}{c} \text{Sm} \\ \bullet \end{array} \right) \rightarrow \text{CrX} \left(\begin{array}{c} \text{X} \\ \bullet \end{array} \right).$$

We obtain a sequence of complexes

$$0 \rightarrow \left[\begin{array}{c} \text{X} \\ \bullet \\ \text{crx} \end{array} \right] \xrightarrow{\iota} \left[\begin{array}{c} \text{Sm} \\ \bullet \end{array} \right] \xrightarrow{\delta_-} \left[\begin{array}{c} \text{Sm} \\ \bullet \end{array} \right] \xrightarrow{\Phi} \left[\begin{array}{c} \text{Sm} \\ \bullet \end{array} \right] \xrightarrow{\delta_+} \left[\begin{array}{c} \text{Sm} \\ \bullet \end{array} \right] \xrightarrow{\pi} \left[\begin{array}{c} \text{X} \\ \bullet \\ \text{crx} \end{array} \right] \rightarrow 0$$

which is degreewise **absolutely exact**.

\rightsquigarrow The **“bulk”** part should be determined by the **“edge”** part.

Generalized 9-lemma

Proposition 3.6 (Generalized 9-lemma (absolute version))

If $X^{i,j}$ is a bounded bicomplex which is **absolutely exact** on each **fixed vertical degree**, then $\forall p+1 < q$ there is a morphism

$$\Xi : \text{Tot}(\sigma_{\mathbb{H}}^{\geq q} X) \rightarrow \text{Tot}(\sigma_{\mathbb{H}}^{\leq p} X)[1]$$

of chain complexes such that

$$\text{Cone}(\Xi) \simeq \text{Tot}(\sigma_{\mathbb{H}}^{\geq p+1} \sigma_{\mathbb{H}}^{\leq q-1} X) \quad .$$

Sketch

- 1 We have an isomorphism

$$\text{Tot}(X) \cong \text{Cone} \left(\text{Tot}(\sigma_{\mathbb{H}}^{\leq q-1} X)[1] \xrightarrow{\widehat{\varphi}_q} \text{Tot}(\sigma_{\mathbb{H}}^{\geq q} X) \right)$$

with LHS **contractible**.

$\rightsquigarrow \widehat{\varphi}_q$ is a homotopy equivalence.

- 2 We also have an isomorphism

$$\text{Tot}(\sigma_{\mathbb{H}}^{\leq q-1} X) \cong \text{Cone} \left(\text{Tot}(\sigma_{\mathbb{H}}^{\leq p} X)[1] \xrightarrow{\widehat{\varphi}_p} \text{Tot}(\sigma_{\mathbb{H}}^{\geq p+1} \sigma_{\mathbb{H}}^{\leq q-1} X) \right)$$

- 3 Combining 1 and 2, we obtain the following **distinguished triangle** in the homotopy category:

$$\text{Tot}(\sigma_{\mathbb{H}}^{\leq p} X)[1] \xrightarrow{\widehat{\varphi}_p} \text{Tot}(\sigma_{\mathbb{H}}^{\geq p+1} \sigma_{\mathbb{H}}^{\leq q-1} X) \xrightarrow{\widehat{\varphi}_q \circ i} \text{Tot}(\sigma_{\mathbb{H}}^{\geq q} X)[-1]$$

\rightsquigarrow required Ξ obtained by **rotating** the triangle. □

Proof of Main Theorem II

Theorem 3.7

G : a singular link-like graph with a unique double point.

\rightsquigarrow There is a morphism $\Xi : [[G]]_{\text{crx}}[2] \rightarrow [[G]]_{\text{crx}}[-2]$ such that

$$[[G]] \cong \text{Cone}(\Xi) \quad .$$

Applying the TQFT $Z_{0,0}$, we finally obtain Main Theorem II.

Main Theorem II

D : a **singular link diagram** with **exactly one double point**.

$\rightsquigarrow \exists$ chain complex $C_{\text{crx}}^{*,*}(D)$ together with a (graded) endomorphism

$$\Xi : C_{\text{crx}}^{*-2,*-2}(D) \rightarrow C_{\text{crx}}^{*+2,*+4}(D)$$

such that

$$C_{Kh} \left(\begin{array}{c} \text{X} \\ \text{X} \end{array} \right) \simeq \text{Cone}(\Xi) \quad .$$

Remark

Main Theorem II **categorifies** the equation

$$V_L(e^{\frac{2\pi}{3}\sqrt{-1}}) = (-1)^{\#L-1} \quad .$$

\therefore Taking the Euler characteristics in Main Theorem II (cf. $q = -t^{1/2}$),

$$\begin{aligned} \chi \left(Kh \left(\begin{array}{c} \text{X} \\ \text{X} \end{array} \right) \right) - \chi \left(Kh \left(\begin{array}{c} \text{X} \\ \text{X} \end{array} \right) \right) \\ = (q^4 - q^{-2}) \chi \left(H^* C_{\text{crx}} \begin{array}{c} \text{X} \\ \text{X} \end{array} \right) \quad , \end{aligned}$$

which belongs to the ideal generated by $(1 - t^3)$.

\rightsquigarrow Crossing change does not affect the value at $t = \sqrt[3]{1}$.

Application

Reducible crossing

Theorem 4.1

The **genus-one** morphism $\widehat{\Phi}$ is a homotopy-equivalence for **reducible** (aka. **nugatory**) crossing; i.e.

$$\widehat{\Phi} : \left[\left[\begin{array}{c} \boxed{D'} \quad \boxed{D''} \\ \diagup \quad \diagdown \\ \diagdown \quad \diagup \end{array} \right] \right] \xrightarrow{\sim} \left[\left[\begin{array}{c} \boxed{D'} \quad \boxed{D''} \\ \diagup \quad \diagdown \\ \diagdown \quad \diagup \end{array} \right] \right] .$$

Proof

By the **categorified Vassiliev skein relation**,

$$\widehat{\Phi} : \text{homotopy equivalence} \iff \left[\left[\begin{array}{c} \boxed{D'} \quad \boxed{D''} \\ \diagup \quad \diagdown \\ \diagdown \quad \diagup \end{array} \right] \right] \simeq 0 .$$

On the other hand, we have $\left[\left[\begin{array}{c} \boxed{D'} \quad \boxed{D''} \\ \diagup \quad \diagdown \\ \diagdown \quad \diagup \end{array} \right] \right]_{\text{crx}} = 0$.

(\because no crux map) □

Corollary 4.2

The universal Khovanov complex satisfies a **homotopy FI relation**:

$$\left[\left[\begin{array}{c} \text{loop} \\ \bullet \end{array} \right] \right] \simeq 0 .$$

Homology of twist knots

Theorem 4.3 (Y. arXiv:2007.15867)

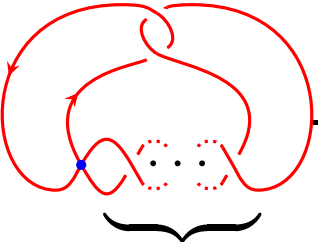

There is a homotopy equivalence

$$\left[\begin{array}{c} \text{Diagram of a knot with } r \text{ negative crossings} \\ r \text{ negative crossings} \end{array} \right] \simeq \begin{cases} \llbracket \text{unknot} \rrbracket \oplus \bigoplus_{i=1}^{r/2} C(2i-1) & \text{if } r \text{ is even,} \\ \llbracket \text{trefoil} \rrbracket \oplus \bigoplus_{i=1}^{(r-1)/2} C(2i) & \text{if } r \text{ is odd,} \end{cases}$$

here $C(k)$ is the complex of the form

$$\cdots \rightarrow 0 \rightarrow S^1 \xrightarrow{\mu\Delta} S^1 \rightarrow \underbrace{0}_{-k - (-1)^k} \rightarrow S^1 \xrightarrow{\mu\Delta} S^1 \rightarrow 0 \rightarrow \cdots$$

Sketch

- 1 Induction on r using $G(r) :=$ 

r negative crossings
- 2 Observe $\Xi = 0$ on $G(r)$ for the degree reason.
- 3 $G(r)$ -crux map α values -1 on the horizontal twists.
 $\rightsquigarrow \llbracket G(r) \rrbracket_{\text{crx}}$ **does not depend on r** up to shifts.
- 4 Compute $\llbracket G(r) \rrbracket_{\text{crx}}$.
 \rightsquigarrow the half of $C(k)$ appears.
- 5 Verify the splitting in each induction step.
